Hepatoprotective effect of *Plumbago indica* root extract on thioacetamide-induced liver damage in rats

Binil Eldhose, Vicente Notario, Jayesh Kuriakose, M.S. Latha

Abstract
Experiments were designed to establish the hepatoprotective activity of *Plumbago indica* (PLBM) methanolic root extracts at different doses (100 and 200 mg/kg bw) against thioacetamide-induced liver damage in albino Wistar rats. Hepatotoxicity was assessed by evaluating the activity of liver-function marker enzymes such as aspartate transaminase, alanine transaminase, alkaline phosphatase and lactate dehydrogenase as well as antioxidant enzymes such as catalase, glutathione peroxidase, glutathione reductase, glutathione-S-transferase and reduced glutathione. Lipid peroxidation was measured as malonaldehyde, a thiobarbituric acid reactive substance. Liver histopathological changes were also evaluated. PLBM administration was found to markedly prevent the elevation of serum liver enzymes and conjugated dienes, and significantly increase hepatic levels of antioxidant markers. Histological findings also confirmed the PLBM protective effects on thioacetamide-induced hepatotoxicity. Thus, results from the present study demonstrate the antioxidant and hepatoprotective activity of PLBM, strongly suggesting that it could be used as a rich source of natural antioxidants.

Keywords: *Plumbago indica*, Thioacetamide, Liver damage, Antioxidants, Lipid peroxidation, Hepatoprotective effect.

1. Introduction
Plants and their derivatives have been utilized as medicines for thousands of years [1]. In recent times, there have been an upsurge of significance in the preventive potential of medicinal plants as antioxidants in scavenging free radical-induced tissue injury [2]. Even though synthetic antioxidants are readily available, they may cause genotoxicity and carcinogenicity at high concentrations [3, 4, 5]. Nowadays more attention has been paid to the preventive effects of natural antioxidants against drug-induced toxicities since herbal medicines are considered as less toxic and free from side effects [6]. The liver has a remarkable ability to metabolize and aid in the excretion of xenobiotics. Nevertheless, it is susceptible to damage from a number of drugs and toxins. Plant-based hepatoprotective drugs are found to be effective against liver disorders due to their safety, efficacy and cost effectiveness. This caused a sharp rise in the use of medicinal plants in recent years [7, 8, 9].

*Plumbago indica* is a medicinal plant member of the Plumbaginaceae family, which comprises 10 genera and 280 species, some being well known for their therapeutic properties. *P. indica* root extract is widely used due to its medicinal properties such as anti-fungal activity [10], antibacterial [10, 11], antiparasitic [12], antifertility [13] and antitumor [14] activities. However, no comprehensive evidence has yet been documented for the hepatoprotective activity of *P. indica* experimentally or clinically. The aim of this work was to study and gain insight on the
biochemical effects and antioxidant profile exerted upon *P. indica* crude methanol extract (PLBM) administration to rats with thioacetamide (TAA)-induced liver damage. Our data will provide information supporting the use of *P. indica*-derived extracts as potent antioxidants against hepatotoxicity.

2. Materials and Methods

2.1. Chemicals and Reagents

Thioacetamide (TAA) was purchased from Sigma-Aldrich (St. Louis, MO). Assay kits were purchased from Agappe Diagnostic, India. All other chemicals were of analytical grade.

2.2. Collection and preparation of plant extracts

*P. indica* roots were collected from the Agricultural Centre, Odakkally, Kerala, and authenticated. A voucher specimen (SBSBR.11) is maintained in the School of Biosciences, Pharmacognosy laboratory, Mahatma Gandhi University, Kottayam. Roots were cleaned, chopped, shade-dried and powdered. Dried powder (50g) was soxhlet extracted with 400 ml of methanol for 48 h. Methanolic extracts were concentrated under reduced pressure using a rotary evaporator and then kept under 4 ºC refrigeration.

2.3. Animals and diets

Male albino Wistar rats weighing 158 ± 6.3 gm (mean ± S.D, n = 30) were used in this study. Animals were housed in polypropylene cages, given standard rat chow (Sai Feeds, Bangalore, India) and drinking water, and maintained under controlled temperature (26-28 ºC), with a 12 h light/12 h dark cycle. Animal studies were performed according to Institute of Animal Ethics Committee (IAEC) regulations approved by the Committee for the Purpose of Control and Supervision of Experiments on Animals (CPCSEA).

2.4. Preparation of doses and treatments

TAA suspended in normal saline was administered at 100 mg/kg body weight (bw) subcutaneously (sc) to induce oxidative stress in rats [15]. Silymarin (Nupal drugs, India), at 20 or 40 mg/kg body weight (bw) subcutaneously (sc) to induce oxidative stress in rats [15]. The homogenates were centrifuged at 3000 rpm for 20 min at 4ºC, and the supernatant was used for the estimation of catalase (CAT), glutathione peroxidase (GPx), glutathione reductase (GR), glutathione-S-transferase (GST), reduced glutathione (GSH) and 1-chloro-2,4-dinitro benzene (CDNB) [19]. The level of lipid peroxidation was measured as malondialdehyde (MDA), a thiobarbituric acid reacting substance (TBARS) and conjugated dienes (CD).

2.5. Experimental design – Preventive study

Animals were divided into five groups, with six rats in each of the groups, which were treated as follows:

- **Group I** : Control rats (vehicle only)
- **Group II** : Thioacetamide control (100 mg/kg bw, subcutaneous)
- **Group III** : Thioacetamide (as in group II) + Silymarin (100 mg/kg bw, peritoneal)
- **Group IV** : Thioacetamide (as in group II) + PLBM (100 mg/kg bw, peritoneal)
- **Group V** : Thioacetamide (as in group II) + PLBM (200 mg/kg bw, peritoneal)

All groups except group I received a single dose of TAA on the ninth day of the experiment. Group III received Silymarin, and groups IV and V received PLBM, nine days before TAA challenge. Group I animals were used as vehicle controls, and received normal saline instead of drug and/or TAA. All animals were sacrificed 24 h after TAA administration.

2.6. Estimation of marker enzymes

Hepatotoxicity was assessed by quantifying the serum levels of aspartate transaminase (AST) (EC.2.6.1.1), alanine transaminase (ALT) (EC.2.6.1.2), alkaline phosphatase (ALP) (EC.3.1.3.10) and lactate dehydrogenase (LDH) (EC.1.1.1.27) by a kinetic method using a kit from Agape Diagnostic Ltd., India. Activities of these serum enzymes were measured by using a semi-autoanalyser (RMS, India).

2.7 Tissue analysis

Livers were excised and washed thoroughly in ice cold saline. Ten percent of the livers weight were used to prepare homogenates in 0.1 M Tris-HCl buffer (pH 7.4). The homogenates were centrifuged at 3000 rpm for 20 min at 4ºC, and the supernatant was used for the estimation of catalase (CAT), glutathione peroxidase (GPx), glutathione reductase (GR), glutathione-S-transferase (GST), reduced glutathione (GSH) lipid peroxidation (as thiobarbituric acid reactive substance, TBARS) and conjugated dienes (CD).

2.8. Histopathological analysis

Small pieces of liver tissues were fixed in 10% buffered formalin and processed for embedding in paraffin. Sections of 5-6 µm were cut and stained with hematoxylin and eosin and examined for histopathological changes under the microscope (Motic AE 21, Germany) by taking microphotographs using a Moticam 1000 camera at the original magnification of 100X. Liver sections were graded numerically to assess the degree of histological features in acute hepatic injury. Centrilobular necrosis is the necrosis around the central vein characterized by the prominent ballooning, swollen granular cytoplasm with fading nuclei. Bridging hepatic necrosis is a form of confluent necrosis of liver cells linking central veins to portal tracts or portal tracts to one another [23].

2.9 Statistical analysis

The results of the analysis were expressed as mean ± SD and all statistical comparisons were made using one-way ANOVA tests followed by Turkey’s post hoc analysis, and *P*-values over than or equal to 0.05 were considered significant.

3. Results

3.1 Preventive effect of PLBM as shown by the measurement of serum biochemical parameters

Rats administrated with TAA showed elevated levels of serum AST, ALT, ALP and lipid peroxides. Treatment with PLBM at doses of 100 and 200 mg/kg significantly (*p* ≤ 0.05) protected the animals from TAA induced hepatotoxicity. Standard drug...
Silymarin also showed a remarkable protection towards TAA administration. Treatment with 100 mg/kg bw of PLBM and Silymarin caused a protection reduction of 92.9% and 83.1% respectively. Treatment with 100 mg/kg bw of PLBM and Silymarin also showed a remarkable protection towards TAA on TAA-intoxicated rats, which illustrates a significant raise (Table 2 shows the preventive hepatoprotective effect of PLBM and Silymarin at 100 mg/kg bw of PLBM along with TAA resulted in a drastic decline (p ≤ 0.05) in the concentration of TBARS during TAA treatment as compared with the vehicle control. Administration of 100 mg/kg bw of PLBM along with TAA resulted in a drastic decline (p ≤ 0.05) of TBARS and CD in the liver compared with the corresponding TAA treated group. Silymarin and 200 mg/kg bw of PLBM also lowered the level of TBARS and CD when compared with the TAA treated group.

3.2. Preventive effect of PLBM as shown by measurement of liver antioxidant parameters

Table 2 shows the preventive hepatoprotective effect of PLBM and Silymarin at 100 mg/kg bw of PLBM and Silymarin significantly increased GR to 93.6% and 65%, GPx to 87% and 63.3%, GSH to 83.1% and 66.2%, SOD to 73.6% and 50.7%, and CAT to 82.8% and 67.5%. Among the two doses of PLBM, 100 mg/kg bw showed maximum enhancing effect, which was almost comparable to those detected in the normal control and Silymarin-treated animals (Table 2).

Table 2: Preventive effects of PLBM against TAA induced changes in serum enzyme levels of rats treated with TAA. Values are mean ± SD, n = 6 animals. † p ≤ 0.05 vs. TAA control

Table 2 shows the preventive hepatoprotective effect of PLBM on TAA-intoxicated rats, which illustrates a significant raise (p ≤ 0.05) in the concentration of TBARS during TAA treatment as compared with the vehicle control. Administration of 100 mg/kg bw of PLBM along with TAA resulted in a drastic decline (p ≤ 0.05) of TBARS and CD in the liver compared with the corresponding TAA treated group. Silymarin and 200 mg/kg bw of PLBM also lowered the level of TBARS and CD when compared with the TAA treated group.

3.3. Histopathological analysis

Histopathological examination of liver sections of normal animals showed normal cellular architecture with distinct hepatic cells, sinusoidal spaces and a central vein (Fig. 1A). The liver sections from the rats of TAA control group showed disarrangement of normal hepatic cells with high degree of damage, characterized by the centrilobular necrosis, focal necrosis and bile duct proliferation (Fig. 1B). The sections from the rats treated with the PLBM (100 and 200 mg/kg bw) and intoxicated with TAA exhibited less centrilobular necrosis and bile duct proliferation compared to the TAA control (Fig. 1C and 1D). PLBM at 100 mg/kg bw showed better activity than at the higher 200 mg/kg bw dose. However, the use of standard Silymarin at 100 mg/kg bw on animals intoxicated
with TAA resulted in slight centrilobular fatty changes, necrosis and bile duct proliferation, indicating its mild toxicity (Fig. 1E).

(A) Normal control; (B) TAA control (100 mg/kg, sc); (C) Silymarin (100 mg/kg bw + TAA); (D) PLBM (100 mg/kg bw + TAA); (E) PLBM 200 mg/kg bw + TAA).  

### 4. Discussion

Natural compounds that diminish free radical formation might be good candidates for the treatment of oxidative damage in cells and tissues. The formation of free radicals may contribute to oxidative damage, resulting in acute hepatitis. TAA has been widely used to induce hepatotoxicity in experimental animals due to its ability to form a toxic reactive intermediate called thioacetamide s-oxide through metabolic activation by cytochrome P-450 enzymes in liver microsomes, which is accompanied by elevated levels of liver enzymes that are released into the blood stream. One of the most notable signs of TAA administration is hepatotoxicity. The goal of this study was to investigate the role of PLBM extract on liver injury produced after TAA-administration to male albino Wistar rats. Results showed that administration of TAA significantly elevated the levels of ALT, AST, ALP and LDH in the animals, leading to the leakage of enzymes to the blood circulation. Administration of PLBM ahead of TAA reduced the elevated enzyme levels in serum plasma resulting from the stabilization of three enzymes, clearly showing a preventive effect of PLBM on TAA intoxication. Reduction in hepatic antioxidant levels is the main mechanism of TAA action. GSH, CAT, SOD, GR and GPx are considered as the first line of the cellular antioxidant defense system. Reduced levels of GSH have been associated with TAA-induced hepatitis and are closely correlated to the lipid peroxidation and disturbance of Ca²⁺ induced by toxic agents. There is an observed boost in tissue GSH content in PLBM-treated group showing that PLBM tends to reverse the tissue depletion of GSH in hepatic tissues. Our findings also show that PLBM stabilizes the GR activity levels in hepatic tissues, which demonstrate the role of PLBM in the recovery of the levels of GSH in tissues, as GR is critical to maintain GSH levels. PLBM causes a significant increase in hepatic SOD and CAT activities and, thus, diminishes the oxidative injury in the liver due to the free radical establishment by the action of TAA. Lipid peroxidation is considered as one of the important characteristics of oxidative stress. Rats treated with TAA showed significantly elevated levels of lipid peroxidation (LPO), which is characterized by increase in the levels of TBARS and CD resulted in the failure of the antioxidant defense mechanism. There was a decrease in the levels of TBARS and CD in PLBM-treated rats previously to their intoxication with TAA, showing that PLBM may exert a preventive action on hepatic tissue. Of the two doses of PLBM used in this study (100 mg/kg bw and 200 mg/kg bw), the lower concentration exhibited a more pronounced, significant effect, reverting the levels of most enzyme activities and antioxidant markers to almost those detected in normal controls. Histopathological evaluation of liver sections from TAA treated rats revealed deep centrilobular necrosis while those from the animals previously treated with PLBM showed clear signs of the preventive action of PLBM against TAA-induced damage. Taken together, results from this study provide solid evidence indicating the efficacy of PLBM as a promising anti-hepatotoxic agent.

### 5. Conclusion

Results from this study demonstrate the hepatopreventive activity of methanolic root extract of *P. indica* in TAA-induced hepatotoxicity, which is likely due to scavenging of free radicals by enhancing the activity of endogenous antioxidants. The antioxidant effects of the plant extract may be attributed to the presence in the extract of phytochemicals such as alkaloids and polyphenols, as we demonstrated earlier. The biochemical parameters altered by TAA administration were reversed towards stabilization at near-normal levels by PLBM, and its effect was more prominent when using 100 mg/kg bw PLBM, when compared with Silymarin which was used as a positive control drug against TAA-induced hepatotoxicity. In
order to further confirming the hepatoprotective action of PLBM, further studies and clinical trials are required, which are already ongoing in our laboratory.
