Scope of onion seed production in Raichur district of Karnataka: A review

Ashok, Basave Gouda and Rakesh C Mathad

Abstract
Onion is grown widely in different parts of the country. It is important foreign exchange earning crop to the country. India produces around 168 lakh tons of onion annually ranking second in the world. The production has increased more than five times during past three decades. The reason for an increase in production is mainly due to increase in area under onion cultivation from 1.94 lakh ha during 1974-75 to 10.51 lakh ha in 2012-13. India possesses many innate advantages over other onion producing countries - its large genetic base, varied soil and climatic conditions and skilled human power. So many farmers are involved in the traditional onion seed production in Raichur district, Karnataka state. They are producing seeds with less cost and getting higher returns from the onion seed marketing to neighbour farmers.

Keywords: Onion, Seed Production, Direct sowing and Seed yield

1. Introduction
Onion (*Allium cepa* L.) is one of the important commercial vegetable crop grown in India. It is widely grown in different parts of the country mainly by small and marginal farmers. It is used as a salad or cooked in various ways in all curries, fried, boiled or baked. It is also used in processed forms *e.g.* flakes, powder paste, pickles *etc.* It has very good medicinal value. Nutritive value of onion varies from variety to variety. Small size onions are more nutritive than big ones. Its major value is in its flavour. Onion ranks medium in calorific value, low in protein and very low in vitamins. The high demand of onions within the country and for the export has made it essential to supply onions round the year either from fresh harvest or from stock.

Among the different onion growing states, Maharashtra tops in an area and production, followed by Karnataka, Madhya Pradesh and Andhra Pradesh. Maharashtra has highest share both in area (24.73%) and production (27.72%). However, the productivity is still low. Poor soil fertility, use of low level of inputs like manures, fertilizers and crop protection chemicals, high labour cost and crop loss due to diseases, lack of resistant varieties and postharvest losses are the major reasons for low productivity.

Medicinal value
The compound is allyl propyle disulfide, sometimes called allyl sulfide. It contains 43.6 per cent sulphur. Some varieties (more pungent) show more than twice as much volatile sulphur as others. Red colour of onion is due to anthocyanin while yellow due to quercitin.

Onion production sometimes hampers due to the scarcity of seed. A lot of work has been conducted on onion bulb production but a little information is available on quality onion seed production. The reasons for lower productivity of onion in India could be attributed to the limited availability of quality seed and lack of development of hybrids in onion is the major limiting factors among the others.

Status of requirements and supply of quality seed of onion in India
The estimated requirement of quality seed of onion is 3120 t (assuming seed rate 6 kg/ha) during 2002 and out of that only 9.6% of the demand is catered by public sectors organizations *viz.* NHRDF, NSC, ICAR institutes (IARI & IIHR) and SAU’s). The most of the demands of the quality seed were either meet by private sectors or unorganized program or own saved seed. Therefore, it becomes important to increase the supply of quality seed through the efficient use of the technology. On the other hand, sincere efforts should be made for the development and release of hybrids.
Floral biology and pollination in Onion

Anthesis occurs in early morning (6-7 hrs). Anther dehiscence is between 7.00 and 17.00 hr and on next day also with peak between 9.30 and 17.00 hr. Pollen fertility is highest on the days of anthesis. Stigma receptivity is also high on the day of anthesis (Jones, 1933) [6]. The duration of anthesis is approximately 4 weeks on individual umbel. The anthesis begins from outer flowers and goes centerally in succession. The flower is protandrous in nature and stigma becomes receptive when shedding of pollen is over (Fig.1). Onion is cross-pollinated in nature and bees, flies and other insects do pollination. It is essential to ensure that there is sufficient population of pollinating insects to achieve the full potential of onion seed. It is also possible in some situation to encourage the development of increased blowfly population by distributing suitable carrier or dried fish among the flowering crop (Currah and Proctor, 1990) [4].

Isolation in onion seed crop: Onion seed field shall be isolated from contaminants viz; fields of other varieties and the fields of the same variety not confirming to varietal purity requirement for certification at least 5 m for foundation seed and certified seed during months bulb production and 1000 m and 500 m for foundation and certified seed production respectively during seed production. However, the maximum permissible limit for bulb not confirming to the varietal characteristics is 0.10 per cent and 0.20 per cent (by numbers) for foundation and certified seed during mother bulb production. The maximum permissible limit of off-types is 0.1 per cent and 0.2 per cent for FS and CS at and after flowering during seed production. Onion seed crop must also be isolated from any flowering multipliers types of onion and shallots.

Nutrition: The ratio of N: P: K applied during seedbed preparation should be 1:2:2 but the nitrogen ratio can be increased according to the status of the soil. Very limited work has been reported on the effects of nutrition in the first year on seed production in the second year. Ahmed (1982) [1] showed that application of N: P: K @ 150 kg ha\(^{-1}\) produced the largest bulbs and highest total bulb yield at the end of first year and that supplementary N application not exceeding 100 kg ha\(^{-1}\) in second year applied during anthesis enhanced seed quality. Higher levels of N increased the seed yield both at the expense of seed quality. The high K levels during bulb production were carried over to the second year and enhanced seed quality. During, mother bulb production the deficiency of copper or manganese should not be allowed. The deficiency of copper is indicated by bulbs of poor colour with thin, fragile scales that come off in handling. Therefore, the application of 80-120 kg powdered copper sulphate control the deficiency.

Sowing: The seeds from approved source is produced and sown at the rate of 8 to 10 kg/ha in the nursery for raising seedlings. Sowing is done in the month of October or November. Seedlings of 8 to 10 weeks old are ready for transplanting. Such seedlings are transplanted in small beds 10-15 cms apart.

Harvesting: Well matured bulbs should be harvested when tops are druped and leaves are still green. After harvesting, bulbs should be thoroughly selected for curing. The time required for curing depends on weather condition i.e. 3 to 4 weeks.

Storage: Well matured, dried and cured bulbs are taken for storage. Such bulbs are stored in well ventilated storage. The shallow trays with performed bottoms are used. The temperature range should be 0 to 5 0 C for 3 to 4 weeks prior to planting and may be increased upto 10 0 C thereafter.

Disadvantages of seed-to-seed method: 1. Seed yield is very less-since bolting is not uniform and all the bulbs may not set 2. Quality of the seed is low

b) Seed Production (Bulb-to-Seed): This method involves producing bulbs from seed in the first season and producing seed from graded bulbs from the previous season.

First season: Seed-to-bulb (Mother bulb production)

Climate: Seed to bulb method can be taken in kharif season
where seeds are sown to get bulbs. For good vegetative growth need low temperature and short photoperiod. For better bulb development need high temperature and long photoperiod.

**Soil:** to produce good quality bulbs need sandy loam to silt loam to clayey soils. Soil pH should be between 5.8 to 6.5.

**Sowing methods and seed rate:** There are three methods for producing good bulbs.

**Drill sowing:** Recommended method for medium sized bulb production as it ensure thick sowing by restricting spacing. Seed rate required is 5.0 kg/ha.

**Broad casting:** Followed when there is late sowing. Seed will be sown by mixing with fertilizer or sand.

**Transplanting:** This method is improved one where nursery is raised and seedlings will be ready in 6-7 weeks. Transplanting is done on either flat beds or ridges and furrows.

**Nutrition:** The recommended dose of fertilizer is 125:62.5:62.5 NPK/ha along with minimum 25 t/ha of FYM. 50% of the N will be applied at field preparation and remaining at 35-40 days after sowing. Never apply fertilizer at bulb formation stage since bulbs may loose shelf life. Shelf life of onion bulbs is very important as these will be used to produce seed during rabi season.

**Irrigation:** Drip irrigation or sprinkler irrigation at eight days frequency with not less than 8-10 times required. Care must be taken to seed that no moisture or water stress at bulb development as it affect seed production in second season.

**Weed management:** Prone to weeds since thickly populated. Hand weeding is very expensive - hence weedicides are recommended. Weedicides like oxyflorofen @ 1ml/L as both pre and post emergent sprays.

**Harvesting:** Harvesting stage is very important due to storage of first season bulbs for seed production. The following points are considered for harvesting.

**Maturity indices:** 50% of neck fall with drying of leaves. At this stage neck thickness become thin and only closed bulbs at neck are to be harvested. Open necks may result in splitting of bulbs during storage.

**Picking:** Picking of bulbs individually and heaped in the field for 3-5 days for curing. After that foliage is cut and dried in the field under shade for 7 days.

**Bulb yield from first season:** 20-30 t/ha

**Second season-Bulb-to-seed (True seed production)**

**Climate:** Bulb to seed method is taken during rabi season since for better and complete bolting required low temperature.

**Selection of bulbs:** Select medium sized bulbs roughly weighing about 30-50 g. Smaller and bigger bulbs are pooled and sold in the market (Fig.2) The bulb weight has markedly influenced the seed production in onion. The increases in bulb weight an increased the seed yield. Although an increase in wt. and size of bulb results in higher seed yield, but very large size bulbs (< 90 gm) if used will need a very high seed rate (60 q/ha). Large size bulbs (3-4 cm diameter) and weighing < 90 gm may seed yield 10.00 q ha⁻¹ Choudhary (1967) [3].

Problems in selection of bulbs: Smallest bulbs produce no bolting and also smaller umbels there by small less vigorous seed. Bigger bulbs produce longer flower stalk which may prone to wind damage.

Avoid- damaged, splits, sprouted and diseased bulbs.

**Shape:** Oval and round shaped bulbs are selected. Flat bulbs need to be discarded.

The bulb are lifted when the 75% plant show neck fall/top die down. The bulbs are dried/curing under naturally ventilated place then neck is trimmed leaving 2-3 cm attached with bulb. The bulbs are roughed at this stage based upon the colour, shape and size. The damaged, twin bulbs and long necked bulbs if any are discarded. The medium size bulbs weighing (50-80 g) bulbs are selected and stored. The bulbs are and examined again before replanting in the following season.

One hectare of bulbs from the first year will plant 3-5 ha for the seed production, the bulbs selected for seed production and usually referred to as mother bulbs. However, the area coverage is greatly affected by storage method and losses occur during storage. The storage temperature also influences seed yield. The temperature ranging from 4.5 to 14°C with an optimum of about 12°C is the best for the storage of mother bulbs that are to be planted for seed production. The plants from such bulbs produce early and heavy yield than those grown from bulbs that have been stored at higher or lower temperature. The roots of the bulbs should be left intact after harvest.
The 13 parts of the bulb are cut before planting to examine the number of glumes, which is related to the compactness, and shape of the bulbs. More the number of glumes flatten the shape and poor the storability. To avoid rotting due to fungal infection of the bulb in field, Bavistin @ 10 gm in 10 lit of water is used for dipping the bulbs before planting. This should be practice in NS/BS seed production

Time of planting in onion crop: The time of planting has great impact over the seed yield and incidence of the disease. Whenever the seed crop is planted in first fortnight of October is subjected to the heavy incidence of diseases and resulting poor seed yield. Tomar and Negi (2002) [10] has recorded the highest seed yield of 576.80 kg/ha with low incidence of diseases and better seed quality in cv. Pusa Madhavi in 15th November planting during rabi 1999. However, the higher seed yield (1251.66 kg/ha) with complete escape from the incidence of disease in cv. Pusa Red was recorded during rabi 2000. Planting of bulbs in ridges and furrows with narrow spacing 20-25 X 15 cm. But the preferred method is to plant on flat beds of 5 X 3.5 m size with 1m space in between. A drip line for every three lines can be laid.

Irrigation in onion seed crop: Hawthorn (1951) [5] found that high soil moisture in the seedling year performed high seed yields. Borgo et al. (1993) [3] reported that water stress during bulb sprouting and beginnings of the anthesis reduce the number of umbels and flowers/plant. However, in practice, the soil surface should not be continuously wet because it will predispose the crop to infection to root rot/damping off. The methods of irrigation also greatly influence the seed yield and seed quality of onion. Tomar et al. (2004) [9] observed that drip method of irrigation gave higher seed yield (894.94 q/ha) than the surface irrigation (648.94 q/ha) in onion cv. Pusa Madhvi. The seed vigour index is also higher in drip (876.49) than surface (663.71) irrigation in onion cv. Pusa Madhvi.

 Roguing: Off types plants having different foliage colour, late maturing bulbs etc are removed during first year and at the time of harvest also, bulbs having different colour, neck thickness and doubleness are rejected. During second year, the plants differing and not conforming to varietal characters are removed.

 Harvesting: The harvesting of seed can start at 110-120 DAS. All the umbels will not come for harvesting at once. Usually 4-5 harvestings are possible. Harvesting can be done when 8-10 black seeds appear in umbels. Delay may result in heavy shattering. Seeds are cleaned by dipping in water for 5 to 10 minutes followed by sun drying.

 Yield: The average yield of 850 to 1000 kg/ha is obtained from good crop.

 Insect pests of Onion and their management: Onion is a most important culinary commodity grown in India. Full yield potential of the crop is not realized due to number of constraints. Among them pest and diseases are the major constraints in onion production. Pest and disease management is crucial for obtaining good quality marketable bulb. Major insect pests and diseases of onion with their symptoms and management practices are given below:

<table>
<thead>
<tr>
<th>Sl. No.</th>
<th>Description</th>
<th>Symptoms</th>

</thead>
<tbody>
<tr>
<td>1</td>
<td>Black Mold (Aspergillus niger)</td>
<td>Post-harvest black discoloration at neck, lesions on outer scale</td>
<td>Wash hands after coming into contact with fungus</td>
<td>Fungus</td>
<td>Seeds to be treated with appropriate fungicide to reduce rot in mature bulbs, storing at temperature below 15 degree Celsius reduces mold from spreading, avoiding bruising bulbs</td>
</tr>
<tr>
<td>2</td>
<td>Botrytis leaf blight (Botrytis Squamosa)</td>
<td>Small white lesions with light green halos which may slightly expand as they age</td>
<td>Disease emergence favours high humidity and warm temperatures, older leaves are susceptible to blighting than younger leaves</td>
<td>Fungus</td>
<td>Allow at least 30 cm spacing between plants to promote good air circulation and quick drying of foliage after rain, appropriate fungicide sprays also required</td>
</tr>
<tr>
<td>3</td>
<td>Downey mildew (Peronospora destructor)</td>
<td>Pale and elongates patches on leaves, leaves turning pale then yellow</td>
<td>Disease emergence favoured by cool temperature and leaf wetness</td>
<td>Fungus</td>
<td>Plant in well-draining areas and don’t over crowd plants, avoid infected plant sets, apply appropriate fungicide and destroy infected crops</td>
</tr>
<tr>
<td>4</td>
<td>Fusarium basal plate rot (Fusarium Oxysporum)</td>
<td>Necrosis begins at leaf tips and move downwards, Wilting plants, infected bulbs may be brown and watery with rot spreading from stem plate to basal leaves</td>
<td>Disease emergence favours moderate to high temperatures</td>
<td>Fungus</td>
<td>Rotate with non-susceptible crops for at least 4 years, plant resistant onion varieties</td>
</tr>
<tr>
<td>5</td>
<td>Pink Root (Phoma terrestris)</td>
<td>Pink roots which darken and turn purple, roots become transparent and water soaked</td>
<td>Fungus colonizes through root tips, fungus can survive in soil down to a depth of 17.7 inches</td>
<td>Fungus</td>
<td>A rotation of 3 to 6 years is preferred, plant more resistant varieties, fumigation can help reduce the pathogen in the soil</td>
</tr>
<tr>
<td>6</td>
<td>Purple Blotch (Alternaria porri)</td>
<td>Severely infected foliage may die, large lesions may coalesce and girdle leaf, killing any tissues between the lesions and leaf tip</td>
<td>Disease emergence favoured by wet foliage, with sporulation occurring in night period on high humidity</td>
<td>Fungus</td>
<td>Fungicides are effective at controlling the diseases but should be rotated for optimal control, Cultural controls includes long rotation and the reduction of leaf wetness by planting in well – drained soil and timing irrigation</td>

Raichur district farmers involved in onion seed production

1. **Shantagouda**: Nagaral, Tq: Lingsugur, Dist: Raichur, M. No.: 9902553839

   a. **Seed to Bulb**
      Variety: Local variety

      Nursery: 21m X 1.5 m, manuring is done with FYM and Cow Urine, 500 m² nursery is sufficient for ½ acre, 2 hand weeding

      Sowing: Last week of April, Broadcasting

      Transplanting: 45-50 days after sowing old seedlings are transplanted to main field

      Main field: Ridges and furrows with two sides

      Spacing: 15 X 10 cm²

      Irrigation: once in six days for sandy soil and once in 10-12 days for clayey soil

      Weeding: 3 hand weedings

      Harvest: 100-110 days after transplanting

      Bulb yield: 10-15 q/ ½ acre

   b. **Bulb to seed**
      Planting: November, ¼ portion of the bulbs are removed and used for planting

      Spacing: 50 X 25 cm², Ridges and furrows with onside planting

      Bulb selection: Medium sized bulbs are selected with multiple sprouts

      Manures: FYM and Cow Urine

      Harvest: 15-20% of the crop should be dried, 120-130 days after transplanting, Harvesting of umbels should be done three times how the flowers attain maturity, Harvested umbels are sun dried for one day and shade dried for two days. Umbels are threshed by stick beating.

      Seed yield: 120-150 kg/ ½ acre.

2. **Ranganna**: Kottadoddi, Tq: Deodurga, Dist: Raichur, M. No.: 9900965693

   a. **Seed to bulb**
      Direct sowing: Seeds are directly sown by broadcasting in main field with the bed size 1 X 15 m² during May month, here duration for getting bulbs is reduced compared to transplanting method and labour cost is also reduced so that less cost of cultivation and yield is also high in case of direct sowing.

      Variety: Rajolli local

      Manures: DAP is mixed with seeds and used for sowing and again DAP is applied to the soil at the time of bulb initiation.

      Weeding: Weedicide Pendamethalin @ 4 ml/l of water spray as a pre-emergent, oxy-chloropyrophos @ 2ml/l of water as post-emergent and 2-3 hand weedings.

      Harvesting: Maturity index is part of the crop should be lodged, 100-110 days after sowing

      Bulb yield: 45-50 q/ acre

   b. **Bulb to seed**
      Planting: Medium sized bubs are selected and bulbs are planted in the month of November

      Spacing: 30 X 30 cm²

      Manures: 2 bags DAP and 1 bag of MOP / acre at the time of planting

      Irrigation: Once in 5-6 days

      Harvesting: March, 120 Days after bulbplanting

      Seed yield: 250-300 kg/acre

3. **Bhaskarareddy** – Ele Bichal, Tq: Dist: Raichur, M. No.: 8762093022
a. **Seed to Bulb**

**Sowing:** May first week

**Nursery:** 7 X 1 m² bed is prepared, 2 hand weedings

**Transplanting:** 30-40 days after sowing old seedlings are transplanted to main field.

**Main field:** 2 X 2 m² plots with ridges and furrows, seedlings are transplanted on both the sides of the ridge.

**Spacing:** 10 X 10 cm²

**Manures:** 2 bags urea and 1 bag DAP/acre

**Weeding:** 3 hand weedings and one post-emergent spray with Oxy-gold

**Irrigation:** once in every 3 days

**Harvest:** The crop is lodged 15-20 % and leaves will dry are the maturity indices for harvesting

**Bulb yield:** 60-70 q/acre

b. **Bulb to seed**

**Planting:** Last week of Nov and first week of Dec, medium sized bulbs are selected for seed production which gives higher yields

**Spacing:** 30 X 30 cm²

**Irrigation:** Once in every 4-5 days

**Manures:** FYM, Urea 2 bags, DAP 1 bag and MOP 1 bag

**Weeding:** 2 hand weedings up to flowering

**Harvest:** The umbels are harvested when they are turned to black and dried

**Seed yield:** 300 kg/acre

---

4. **Badesab- B. Hanamapur, Tq:Dist: Raichur**

a. **Seed to bulb**

**Sowing:** April last week and First week of May

**Nursery:** First raise the nursery 1.5 X 10 m² and transplanted to main field 30 days old seedlings

**Main field:** 3 X 2 m² plots with flatbed

**Spacing:** 15 X 10 cm²

**Manures 3:** tonns/acre FYM, 1 bag urea, 1 bag DAP and 1 bag MOP

**Irrigation:** 6-7 days interval

**Weeding:** Pre-emergent as Penamethalin @ 3 ml/l and post-emergent as Oxy-gold @ 10 ml/l and 2-3 hand weedings

**Harvest:** 120-130 days, lodging and drying of the foliage

**Bulb yield:** 30-45 q/acre

**Bulb to seed**

**Planting:** Medium sized bulbs are selected and planted during October last week and first week of November

**Spacing:** 50 X 30 cm²

**Irrigation:** 4-5 days interval

**Weeding:** 2 hand weedings

**Harvest:** 125-130 days after transplanting, the crop is started to lodge and harvested bulbs are threshed manually by beating with stick after thorough drying in sun

**Seed yield:** 200-250 kg/acre
5. **Veeranagouda- Katakunur, Tq: Dist: Raichur**

   **a. Seed to bulb**

   **Sowing:** Last week of May- first week of June, Seedlings are raised in nursery and transplanted to main field

   **Main field:** 5 X 1 m², seedlings are transplanted to the main field after 45 days of sowing

   **Manures:** FYM @ 2-3 tonns/acre and Urea 2 bags, DAP 1 bag and 1 bag MOP

   **Weeding:** Post-emergent spray with the oxy-gold and 2-3 handweedings

   **Irrigation:** 4-5 days interval

   **Harvest:** When the part of crop is lodged, 110 days after transplanting

   **Bulb yield:** 30 q/acre

   **Bulb to seed**

   **Planting:** In the month of November, Medium to large sized bulbs are selected. Onion seed production is done with the ground nut crop intercropping

   **Spacing:** No specific spacing is maintained

   **Manures:** Urea and DAP each 1 bag/acre

   **Weeding:** 2-3 hand weeding

   **Irrigation:** 7-8 days interval

   **Harvest:** when the crop will start lodging

   **Seed yield:** 70-100 kg/acre

   **Conclusion**

   In our country more than 20% of onion seeds are used from their own farm saved seeds for sowing. Since, from last 20 years the Raichur district farmers are continuously involved in the onion seed production. Farmers are producing seeds in lesser quantities for sowing of their own field in next season. They are supplying the seeds to neighbor farmers and for their own farm.
