Pharmacognostical study of medicinal plants of Western Ghats: Chlorophytum kolhapurens and Chlorophytum bharuchae

Sharma RR and Thakare PV

Abstract
The tuberous roots of Chlorophytum borivilianum is widely used by the folk people in the treatment of variety of diseases as and as a galactogogue and aphrodisiac. Commonly known as ‘Safed musli’. The tuberous roots of other species such as Asparagus and Orchids are sometimes also called as safed musli, leading to confusion. In order to ensure correct botanical standardization, the detailed pharmacognostic study was carried out in present study on the other species of Chlorophytum viz. Chlorophytum kolhapurens and Chlorophytum bharuchae. Macroscopy and microscopy, physicochemical analysis, preliminary phytochemical screening and other WHO recommended parameters for standardization were performed. Physicochemical tests like moisture content, ash value, extractive values and phytochemical screening showed presence of alkaloids, carbohydrates, proteins and saponins gives supplement information concerning its identification. Chromatographic analysis (TLC) confirms the presence of saponins which is a remarkable identification. The microscopic constants, and other physicochemical examinations of Chlorophytum species will be useful in standardization, hence would be of immense value in authentication of plant.

Keywords: Chlorophytum, Pharmacognostic standardization, Phytochemistry, TLC

Introduction
Plants as natural medicines to benefit humans have a long history and ancient civilization, particularly in some nations such as India, China, Egypt, and Greece. The majority of world populations still rely on plant based medicine because of several reasons such as long history of safe use, affordability and easy availability. The growing interest in drugs of plant origin may also be due to several other reasons such as a large section of world's population does not have access to conventional pharmacological treatment and side effects and other problems of synthetic drugs due to incorrect use [1]. Natural product remains a prolific source of discovery of new drugs from the ancient Vedic period. India has long history of management of human health through Ayurveda which came in to existence more than 6000 yrs ago. Charak and Sushruta had contributed a lot in the development of plant based medicine and surgery [2]. In recent years, there has been growing interest in complementary medicine, functional and therapeutic uses of natural products, especially those derived from plants. Thus, natural products including terrestrial and marine plant extracts have become a source of optimism for drug discovery. The rich biodiversity of India has attracted the attention of researcher, which remained untouched as far as the new drug discovery is concerned [3]. Bioactive natural products are generally originates from microbes and plants. As chemicals, natural products include belong to diverse classes viz. terpenoids, steroids, saponins, phenols, flavonoids, alkaloids, amino acids, proteins, carbohydrates, lipids, nucleic acid bases, etc. [4] and some 75% of these were discovered by examining the use of these plants in traditional medicine. Species of Chlorophytum are sold in the market as ‘Safed musli’ due to its white tuberous roots widely used in herbal drug industries. Chlorophytum species plants are found in India, Nepal and Myanmar [5]. In India they are found wild in natural forest and Hilly areas Rajasthan, Gujarat, Madhya Pradesh, Bihar Orissa and West Bengal [6]. They belong to family Asparagaceae are small perennial herbs and are considered to be valuable nerve and general tonic for strength and vigor. Leaves species are edible and use as a vegetable [7]. The aim of present study was to evaluate the various Pharmacognostical characteristics and phytochemicals from Chlorophytum species viz. Chlorophytum kolhapurens and Chlorophytum bharuchae which will help in their identification and authentication.
Materials and methods

Plant material

Chlorophytum kolhapurens and Chlorophytum bharuchae were collected from natural population from Western Ghats of Maharashtra during rainy season. Collected species were identified and confirmed with the herbarium species at Botanical Survey of India (BSI), Pune, Maharashtra.

Microscopic and Macroscopic evaluation

These fresh leaves were used for morphological characters by microscopic and macroscopic methods as studied in Trease and Evans [8]. Thin hand transverse section of fresh leaves of plants were cut and stained with different staining regents and observed under microscope at 45 X objective.

Physicochemical parameter

The various physicochemical parameters such as total ash, acid insoluble ash, water soluble ash, moisture content, specific gravity, extractive value (water and alcohol) have been studied [9].

Preliminary phytochemical analysis

The tubers (roots) of the plants were washed thoroughly with running water to remove dirt. The tubers were than shade dried, powdered using blender and stored in air tight containers. Dried powder (5g) was extracted in Soxhlet reflux extractor with petroleum ether to remove lipids and fatty acids, ethyl acetate and chloroform to remove proteins and hexane to remove fats. The defatted powder was then extracted with methanol for 48 hours [10]. The extracts were concentrated under vacuum rotary evaporator, dried, weight and stored for further investigation. Methanol extracts were chosen for phytochemical screening. Preliminary phytochemical screening was performed to identify phytochemicals present in plant extract using standard procedures [11].

Thin Layer Chromatography (TLC)

The methanolic fractions were further separated by column chromatography on silica gel. The fractions obtained were analyzed by TLC. Analytical TLC plates were prepared by pouring silica gel G and GF slurry on the glass plates. The plates were allowed to dry in air for 30 minutes and then kept in oven at 110°C for 30 minutes. The plates were placed in the developing jar with different solvent system. The resultant chromatograms were observed in UV/VIS. The spots were identified and RF values were calculated [12].

Spot visualization

Concentrated H2SO4 and Ehrlich reagent were used as spraying reagent. TLC plates were heated at 100°C after spraying the reagent. Pinkish-violet spots of saponin were observed under UV/VIS [13].

Screening for Saponin

Foam test: For the test of saponins, extracts were diluted to 5 mL with distilled water and was shook vigorously. Appearance of stable foam was regarded as the presence of saponins.

Froth test: The extracts were diluted with 20 ml distilled water in a test tube and were shook vigorously for 30 seconds. The tube was allowed to stand in vertical position for 30 minutes. If froth was observed above the surface of liquid after 30 min the sample confirms the presence of Saponin.

Haemolytic test: For haemolytic test, the extracts were added to one drop of blood placed on glass side, haemolytic zones appeared was confirmation of haemolysis activity.

Results and Discussions

Chlorophytum bharuchae was distributed in Kolhapur and Aurangabad district in Maharashtra and Karnataka. It was reported as rare species in Maharashtra. Chlorophytum kolhapurens was found to be reported from Kolhapur, Maharashtra. Figure 1 and 2 represents the inflorescence of C.bharuchae and C.kolhapurens.

Macroscopic and Microscopic evaluation

Leaves of Chlorophytum species showed similar morphological and microscopic characters with some differences in leaf length, leaf margin, perianth and number of vascular bundle, number and arrangement of xylem strand.

Physicochemical parameter

Physicochemical study is important, as it helps in characterization of constituent or group constituents that frequently lead to establish the structure-activity relationship and likely mechanism of action of the drug. The results are summarized in table 4; the values are expressed in terms of Mean±SD.

Preliminary phytochemical analysis

The qualitative analysis of methanol extract of Chlorophytum species showed the presence of medicinally active constituents such as alkaloids, carbohydrates, proteins and saponins. Table 2 shows the various phytochemicals present in Chlorophytum kolhapurens and Chlorophytum bharuchae.
Thin Layer Chromatography
Chlorophytum species were subjected to thin layer chromatographic analysis to find the presence of number of chemicals and also to identify the type of saponins. The best separation was observed in solvent system containing CHCl₃: MeOH. The respective solvent systems are depicted in Table 3. Saponins were visualized by spraying 10% sulphuric acid in ethanol and Ehrlich reagent. Saponin produced violet and dark violet spots with 10% sulphuric acid in ethanol whereas Ehrlich’s reagent showed pink or red colored spots, which confirms the presence of saponins (Figure 5).

The species showed the correct taxonomy which is useful for the standardization of drug. The morphological characters, ash analysis, phytochemical screening and the saponins identification test with respect to their Rf values (Table 5). All these investigations will be useful for correct botanical identification and authentication. Also if data is comparable with the above mentioned species of safed musli, the Chlorophytum species can be used as a substitute for them.

Conclusions
The detailed study of Pharmacognostic parameters of C.kolhapurens and C.bharuchae setup the standards which could be beneficial and serves as diagnostic tool for proper authentication of this medicinally important plant.
