Abstract

Six typical pedons from cultivated soils surrounding Ramakrishnapur open cast coal mine area of Mancherial district, Telangana state were evaluated for their suitability to major crops viz., cotton, rice, maize and redgram. The suitability classes ranged from highly suitable (S1) to permanently not suitable (N2) to these crops. All the pedons of Ramakrishnapur were moderately suitable (S2) except pedon 4 was marginally suitable (S3) for cotton. Pedon 1, 2, 3, 5 and 6 were moderately suitable (S2), pedon 4 was marginally suitable (S3) where as pedon 6 was highly sutable (S1) for cotton and redgram. Pedon 1, 3 and 5 were moderately suitable (S2), pedon 6 was marginally suitable (S3) and pedon 4 was not suitable (N2) for rice. Pedons 1, 2, 5 and 6 were highly suitable (S1) and the rest of the pedons were moderately suitable (S2) for maize crop. Drainage, texture, low organic carbon content and low CEC content were severe limiting factors in pedon 4. The limitation levels of land characteristics varied from crop to crop. Suitable conservation and remedial measures were suggested to improve the soil productivity on sustainable basis without deteriorating soil quality. Potential land suitability classes were also given based on the possible improvement of these soils.

Keywords: soil-site suitability, ramakrishnapur, soil taxonomy, limitation levels

Introduction

Land evaluation is the ranking of soil units on the basis of their capabilities (under given circumstances including levels of management and socio-economic conditions) to provide highest returns per unit area and conserving the natural resources for future use. The land suitability evaluation for field crops forms a pre-requisite for land use planning (Sys et al., 1991)^[10]. The population of India has increased from 456 million in 1961 to 700 million in 1980 to 1053 million in 2000 and is projected to reach 1387 million by 2020 and 1665 million by 2050. The per capita cultivable land in India is also reported to decline from 0.34 ha in 1961 to 0.14 ha in 2010 and is projected to further decline to 0.09 ha by 2050 (Lal, 2013). Performance of any crop is largely influenced by soil-site parameters as conditional by climate and topography and management level (Sehgal, 1991)^[11]. Thus, it is essential to interpret the soil-site suitability for major crops grown in the area. However, each plant species requires specific soil and climatic conditions for its optimum growth. Production oriented crop cultivation on appropriate soils (taxonomic unit) appeared to be more beneficial (Bhaskar et al., 1988 and Naidu et al., 1988) ^[12, 13]. Information on soil site suitability for crops in cultivated soils surrounding open cast coal mine area in Ramkrishnapur of mancherial district, Telangana state keeping this in view an attempt has been made to evaluate the soil suitability for major crops viz., for cotton, maize, paddy and redgram on Inceptisols, Entisols and Alfisols.

Material Methods

Ramakrishnapur lies in between 18°54¹ and 18°55¹ north latitudes and 079°23¹ and 079°28¹ east longitudes. The study area consists of sand stone and granite-gneiss parent material. The climate belongs to semi-arid monsoonic with distnict summer, winter and rainy seasons. The mean annual rainfall recorded for the last 10 years (2003-2013) is 1102.90 mm of which constitutes more than 83% was received during June to September. The mean annual temperature was 27°C with mean summer temperature 39°C and the mean winter temperature of 31°C. The maximum temperature recorded for last 10 years is 40°C and the minimum temperature 15°C in the month of December.

The soil moisture regime has been computed as ustic and the soil temperature regime as iso-megathermic. The natural vegetation comprises of Acacia auriculiformis, Azadiracta Indica, Prosopis juliflora, Tectona grandis, Pithakalobia dacli, Tamrindus Indica, Pongamia pinnata etc. The six peodns were studied in detail and the morphological characteristics were presented in table 2. The detailed morphological description of these six pedons was studied in the field as per the procedure outlined in U.S.D.A. soil survey manual Soil Survey Staff 1998 [8]. Later, horizon-wise soils samples were collected and characterized for important physical, physic-chemical properties and available nutrient status using standard procedures. The soils were classified taxonomically (Soil Survey Staff, 2014)^[9] of USDA. These pedons were evaluated for their suitability using limitation method regarding number and intensity of limitations (Sys et al. 1991)^[10]. The landscape and soil requirements for the selected crops were matched with generated data at different limitation levels: no (0), slight (1), moderate (2), severe (3) and very severe (4). The number and degree of limitations suggested the suitability class of pedons for a particular crop (Sys et al. 1991)^[10]. The potential land suitability (table 3) subclasses were determined after considering the improvement measures to correct these limitations (Sys et al. 1991)^[10]. Considering limitations and potentials of the soils based on that a suitable land use plan has also been suggested.

Results and Discussion

Details of pedons and relevant soil characteristics are given in table 1 and site characteristics and weighted means of soil characteristics are given in table 2. These soils are developed from granite-gneiss. The kind and degree of limitations of the soils for the major five crops are presented in table 3. The soils with no or only four slight limitations are grouped under highly suitable class (S1); the soils with more than four slight limitations, and/or with more than three moderate limitations under moderately suitability class (S2); the soil with more than three moderate limitations, and/or one or more severe limitations under marginally suitable (S3) class; the soils with very severe limitations which can be corrected under N1 (currently not suitable); the soils with very severe limitations which cannot be corrected grouped under unsuitable class N2 (Sys et al. 1991)^[10]. This method also identifies the dominant limitations that restrict the crop growth shown in the sub-class symbol such as climatic (c), topographic (t), wetness (w), physical soil characteristics (s), soil fertility (f) and soil salinity/alkalinity (n). The suitability classes and sub-classes were decided by the most limiting soil characteristics (Table 3).

Pedon 1, which is grouped under Typic Haplustepts is moderately suitable for cotton, rice and maize, whereas, it is highly suitable for maize. The major limitations were wetness (drainage), physical soil characteristics (texture) and soil fertility characteristics (CEC) wetness (drainage) was major limiting factor. Whereas, for all four crops soil fertility characteristics was a major limitation factor it can be improved by the application of farm yard manure, green manuring and soil test based fertilizer recommendation should be followed to avoid nutrient imbalance and to supply the right nutrients at right time. Pedon 2, which is grouped under Typic Haplustalfs was moderately suitable for cotton and redgram, highly suitable for maize and it is marginally suitable for rice. The major limitations were wetness, texture, coarse fragments and soil fertility characteristics was major limiting factor rice cultivation, for rice cultivation because it does not allow in maintaining standing water and requires irrigation at frequent intervals. Peodn 3, which is grouped under Typic Haplustepts was moderately suitable for cotton, rice, maize and redgram. The major limitations were drainage, texture and soil fertility characteristics. Pedon 4, which is grouped under Typic Ustrothents was moderately suitable for maize marginally suitable for cotton and redgram whereas, permanently not suitable for rice. The limitations included drainage under wetness, texture and coarse fragments under physical soil characteristics and cation exchange capacity and pH under soil fertilirt characteristics. Pedon 5, which is grouped under Typic Haplustepts was moderately suitable for cotton, rice and redgram. Whereas, highly suitable for maize. The limitations included drainage under wetness, texture and coarse fragments under physical soil characteristics. Pedon 6, which is grouped under Typic Haplustalfs was moderately suitable for cotton, highly suitable for maize and redgram whereas, marginally suitable for rice. The limitations included drainage under wetness, texture, cation exchange capacity and coarse fragments under physical soil characteristics and soil fertility characteristics (Satvavathi and Survanaravan Reddy, 2004)^[7] were reported in Telangana region of Andra Pradesh. All the cultivated areas surrounding open cast coal mine area pedons of Ramakrishnapur were moderately suitable for cotton crop. Patil et al., (2010)^[5] and Madhavi, (2014)^[3] also reported that soils in Lendi water shed of Chndrapur district and Environmental impact assessment (Eia) of coal opencast mining on soil and land resource environs in Telangana region. The cultivated soil pedons 1, 3 and 5 were moderately suitable whereas, the pedons 2 and 6 were marginally suitable and pedon 4 was permanently suitable for rice. Leelavathi et al., (2010)^[2] and Selvaraj and Naidu (2013)^[6] also reported that the soils of Yerpedu and Renigunta mandals in Chittoor district. The cultivated pedons 1, 2, 5 and 6 were highly suitable for maize cultivation. Whereas, pedon 3 and 4 were moderately suitable for maize. Narsaiah (2016) also reported that classification, constraints analysis and crop suitability evaluation of soil and land resources in part of Warangal district in Central Telangana Zone. The cultivated soil peodns surrounding open cast coal mine peodns 1, 2, 3 and 5 were moderately suitable, whereas, pedon 6 was highly suitable and the pedon 4 was marginally suitable for redgram. Narsaiah (2016) also reported that classification, constraints analysis and crop suitability evaluation of soil and land resources in part of Warangal district in Central Telangana Zone.

Wetness (drainage), texture, coarse fragments and cation exchange capacity and pH are limitations in all the pedons poor drainage can be improved by soil conservation measures, growing leguminous crops in rotation and application of organic manures. The pH can be reduced by application of organic manures and soil amendments like sulphur / pressmud / spent wash. Texture is a limitation in pedon 4, light textured soils which also had low water holding capacity, can be improved by addition of tank silt (Pond Mud) along with careful soil and water management practices like mulching or addition of bulky organic manures / green leaf manuring. Similar observations were made and recommendations were suggested by Selvaraj and Naidu (2013)^[6] and Niranjan *et al.*, (2013)^[14] in Renigunta mandal and Pulivendula region of Andhra Pradesh.

Limitations: 0- No; 1- Slight; 2- Moderate; 3- Severe; 4- Very severe

Suitability classes: f- soil fertility limitations; s- Physical soil limitations; w- wetness limitations; n- Salinity (and /or alkalinity) limitations

Conclusion

The crop suitability of cultivated soils surrounding open cast coal mine area of Ramakrishnapur in Mancherial district ranged from highly suitable (S1) to permanently not suitable (N2) for the major crops *viz.*, cotton, rice, maize and redgram. The limitations observed in these soils were physical characteristics like wetness, texture and coarse fragments and fertility characteristics like high pH and low CEC. Remedial measures were suggested to achieve potential productivity of these soils without deteriorating the soil quality and to sustain crop yields.
