Growth and yield of sunflower as influenced by VAM and phosphorus application

Kalaiyarasan C, MV Sriramachandrasekharan, S Jawahar, K Suseendran, R Ramesh, S Ramesh and R Kanagarajan

Abstract

The field experiment was conducted at Experimental Farm, Department of Agronomy, Faculty of Agriculture, Annamalai University, Annamalai Nagar, Tamil Nadu during July – October 2015 to study the effect of mycorrhizal inoculation (VAM) and different levels of phosphorus on growth, yield attributes and yield of hybrid sunflower cv. Sunbred.The experiment was conducted by factorial randomized block design with two replications. The treatments of experiment consisted of 4 levels of P_2O_5 (0,25,50,75 and 100kg/ha) applied in the presence or absence of VAM inoculates. The results revealed that growth, yield attributes and yield was significantly influenced by various P levels in the presence and absence of VAM inoculations. The growth and yield of sunflower was highest under mycorrhizal inoculated plants than non micorhizal inoculation. Among the various phosphorus levels tried, P_2O_5 at 100 kg ha^{-1} recorded maximum values for growth and yield, while P_2O_5at 25kgha^{-1} registered minimum values for growth and yield of sunflower. Among the treatment combinations tried, mycorrhizal inoculation with P_2O_5 @ 100 kg ha^{-1} recorded maximum values for growth and yield attributes and yield of sunflower (2153 kgha^{-1})but it was on par with M_2 P_3 (mycorrhizal inoculation with P_2O_5 @ 75 kg ha^{-1}). The lowest values of growth and yield attributes and yield were recorded by non-mycorrhizal inoculation with P_2O_5 @ 25 kg ha^{-1}.

Keywords: Sunflower, VAM, growth and yield

Introduction

Sunflower (*Helianthus annuus* L.) belongs to the family *Asteraceae*, a new world plant, native of southern parts of United States of America and Mexico has been developed into a valuable source of edible oil and meal, with almost 20-27 per cent protein and 40-47 per cent oil (Saleem *et al*., 2003) [14]. It is easy to cultivate and grown in different conditions and soils. Sunflower oil has excellent nutritional properties, and has a relatively high concentration of linoleic acid (Seiler, 2007) [15]. It is also a wealthy source of vitamins A and D. The sunflower seed cake used for cattle feed which is a good source of protein (Gandhi *et al*., 2008) [6]. Indian soils are deficient in phosphorus. P is generally a limiting factor in sunflower growth and yield because P deficiencies reduce the accumulation of crop biomass (Zubillaga *et al*, 2002) [19]. P is an essential plant nutrient required for higher and sustained productivity of oil from sunflower. Its influence on seed yield, oil yield and oil quality has been well established (Bahl and Toor, 1999) [5]. Phosphorus is one of the most essential element for plant growth after nitrogen. It plays a significant role in several physiological and biochemical plant activities like photosynthesis, transformation of sugar to starch and transporting of the genetic traits. A great advantage of feeding the plants with phosphorus is to create deeper and more abundant roots. Phosphorus causes early ripening in plants, decreating grain moisture, and improving crop quality. However, the availability of this nutrient for plants is limited by different reactions. A great proportion of phosphors in chemical fertilizer becomes unavailable to the plants after its application in the soil and further, the mobility of this element is very slow in the soil and cannot respond to its rapid uptake by plants. This causes the creation and development of phosphorus depleted zones near the contact area of roots and soil in rhizosphere. Therefore, the depletion zones and help to absorb the phosphorus from a wider area by developing an external network around root system. Mycorrhiza has symbiotic association between the soil fungi and roots of higher plants (Smith *et al*., 2010) [16]. These fungi enhance the plant growth through making availability of mineral nutrients such as P, Zn and Cu (Phiri *et al*., 2003) [13]. Colonization of AM fungi in cortical tissues of sunflower increased growth parameters of sunflower (Jalaluddin and Hamid, 2011) [9]. The current trend is to explore the possibility of supplementing chemical fertilizers with organic ones, more particularly biofertilizers of microbial origin. In this context, VAM fungi are receiving greater attention in their beneficial effects on plant growth. Vesicular-arbuscular mycorrhizal (VAM) are widespread in soils, and often the growth of mycorrhizal plants will be higher in comparison to non-mycorrhizal plants. This beneficial effect on plant growth has largely been attributed to higher phosphorus (P) uptake and consequently better P nutrition of mycorrhizal plants (Antunes *et al*. (2007) [3]. The beneficial effects of VAM inoculation on P uptake, growth and yield of sunflower have not been carried out. Hence, the present study was taken up to find out the effect of mycorrhizal inoculation and phosphorus on the growth and yield attributes of hybrid sunflower.

Materials and methods

Field experiment was conducted during July – October 2015 at the Experimental Farm, Department of Agronomy, Faculty of Agriculture, Annamalai University. The experimental soil was clay loam with pH 8.1, OC 5.0g kg-1, available N (235kg ha-1), P (22.1kg ha-1) and K (356kg ha-1).The experiment consisted of eight treatments and was laid out in factorial randomized block design with two replications. The treatments imposed in the experiment are M1-Non inoculated and M2-inoculated Glomusintraradices were tried along with different phosphorus levels (P1-25, P2-50, P3-75 and P4-100 kg P2O5 ha-1) through SSP. Recommended dose of 60:60 kg of NK ha-1 was applied in the form of Urea and MOP respectively. Half the dose of N and entire dose of K were applied basally. The remaining quantity of N was applied at 30 DAS. P was applied as per treatment schedule. The mycorrhizal inoculum was applied near the root zone of sunflower. 2gm VAM was applied per plant by placement method. At harvest, plant height was recorded from the first node at the bottom of the plants to the bottom of the head and expressed in cm. The leaf area index (LAI) was calculated by dividing the total leaf area of the plant by the land area occupied. To estimate dry matter production (DMP) the selected plant samples were collected, washed, air dried and kept in an oven at 80°C till constant weight was obtained and expressed in Kg ha-1.The yield parameters and yield were recorded at harvesting stage of plant. The head samples for yield were also dried to constant weight and threshed mechanically. Seed yield was adjusted to a 10% moisture basis. Filled seeds and empty hulls were separated by hand. Hereafter, grain number head-1 refers to filled grains only. Data collected were subjected to statistical analysis of variance according to Gomez and Gomez (1989).

Results and discussion

Growth attributes

Mycorrhizal inoculated plants significantly influenced the growth attributes viz., plant height, LAI,DMP and CCI (Table 1).Mycorrhizal inoculation recorded the highest plant height at harvest (147.0cm), leaf area index at flowering (4.26), dry matter production at harvest (4994 Kg ha-1) and chlorophyll content index (23.43) at flowering stage than non-mycorrhizal inoculation. This might be due to the formation of external mycelium around the roots by AM fungi which possibly helped to increase the availability of nutrients to the surface of the roots and thereby increased the nutrient uptake and growth of the plant. Similar finding was earlier reported by Kavitha and Nelson (2014) [10].Among the different levels of phosphorus, application of P2O5 at 100 kg ha-1 significantly recorded highest plant height at harvest (153.8 cm), leaf area index at flowering (4.05), dry matter production at harvest (5316Kg ha-1) and chlorophyll content index (24.73) at flowering stage. The lowest values for growth attributes were recorded in the treatment P2O5 at 25 kg ha-1. This might be attributed to the P stimulating effect on root growth and expansion by increasing crop growth rate. Similar findings were earlier reported by Adebayo *et al*. (2010) [2] and Abubaker Ali *et al*. (2014) [1].

The interaction effect between the mycorrhizal inoculation and phosphorus was not significant (Table 2). The treatment combination of mycorrhizal inoculation along withP2O5at 100 kg ha-1 recorded maximum values for growth attributes but it was on par with mycorrhizal inoculation along with P2O5 at 75 kg ha-1.The highest values under these treatments might be due to mycorrhizal inoculation, because this bio fertilizer can enhance absorption of phosphorus by plant. The lowest growth attributes was recorded in the treatment combination of non mycorrhizal inoculation with 25 kg P2O5 ha-1.This could be due to inadequate availability of nutrients. This result is in conformity with the findings of Khirood Doley and Paramjit Kaur Jite (2012) [11].

Yield attributes and yield

Mycorrhizal inoculated plants showed significant influence on yield attributes and yield (Table 1). Mycorrhizal inoculation recorded the maximum head diameter (17.7cm), number of filled seeds head-1 (660), 100 seed weight (5.83 g) and seed yield (1845 kg ha-1) and stalk yield (4069 kg ha-1) than non-Mycorrhizal inoculation. Many researchers suggested that VAM symbiosis increased the units of photosynthesis, and so as to increase the rate of photosynthetic storage and export at the same time (Auge, 2001) [4].

Phosphorus levels significantly influenced the yield attributes and yield (Table 1). Among the different levels, P2O5 at 100 kg ha-1 produced maximum head diameter (18.9cm) number of filled seeds head-1 (730), 100 seed weight (6.06 g) and seed yield (2048 kg ha-1) and stalk yield (4379 kg ha-1). The lowest value for yield attributes and yield was recorded in the treatment P2O5 at 25 kg ha-1.This might be due to the role of phosphorus in cell division and cell enlargement, photosynthesis, which ultimately affect the yield attributes. Similar finding was earlier reported by Ghazanfar Ullah Sadozai (2013) [7].

The interaction effect between the mycorrhizal inoculation and phosphorus was not significant (Table 2). The treatment combination of mycorrhizal inoculation along with P2O5 at 100 kg ha-1 recorded higher values for yield attributes and yield but it was on par with mycorrhizal inoculation along with P2O5 at 75 kg ha-1.This might be due to more availability of phosphorus and other nutrients at both vegetative and reproductive stages. Similar findings were earlier reported by Hossein Soleimanzadeh (2012) [8] and Khirood Doley and Paramjit Kaur Jite (2012) [11]. The lowest values of yield attributes and yield were recorded under the treatment combination of non my corrhizal inoculation with 25 kg P2O5 ha-1.This might be due to the absence of mycorrhiza resulted in reduced growth and yield attributing characters and seed and stalk yield. Similar findings were earlier reported by Ultra Jr*et al*. (2007) [117] and Mostafa Heidari and Vahid Karami (2014) [12].
